I've worked with vCIO at Microsoft since 2006, and vCIO is now. not only add to the noise of the result, but also introduce new artefacts. We experimented with both approaches as a function of the number of isolines, and the smoothing volume size, and found that the latter approach is strongly superior. As a second aspect, we tested the impact of changing the temporal interval between reconstructions, which is known to impact the visual quality of the final result. We tested intervals of 30 min, 15 min, 1h and 6h to ensure that a broad range of quality can be covered. Both the occlusion case and the 3D laser interferometry case were simulated to study the impact on the output of the model. Even though we did not find a clear conclusion, the effect seems to be relatively small with most benefit being observed at the smallest change of the temporal interval. The simulation environment could be extended further to also include light sources and multiple laser scans to study the mutual influence of the various parameters. **Limitations of the simulations.** Of course the model does not directly replicate the real world. The noise level is therefore not realistic, as the current model would not be corrupted by state of the art noise removal techniques such as denoising or constrained reconstruction. Similarly, the simulations do not include noise in the scans, at a level that has become the norm in recent years. And finally, even if
